Radar observations – merits, applications & limitations

Dedicated to Prof. D.R. Sikka- an advocate of quality observation and research; This lecture is on a few of my papers which attracted him.

Also, a tribute to Prof T.N. Krishnamurti, FSU who admired my Radar meteorology work & used the Radar rainrate data by way of physical initialization of a numerical model for Thane cyclone.

suresh.imd@gmail.com

**भारत मौसम विज्ञान विभाग
INDIA METEOROLOGICAL DEPARTMENT**

Topics to be discussed

- Radar observations (& necessity of interpretation of products).
- Variety of applications (Public weather service/ severe weather warnings, **Hail stone detection and warning (for Agriculture ?)**, Aviation, Hydrology,).
- We confine our discussions here to Hydrological application (Rain rate estimation and accumulation over a period of time), **as it is relevant to agriculture.**
- Physical initialization of NWP model - nudging of the latest Radar rain rate using reverse algorithms (reverse Similarity theory, Reverse Cumulus Parametrization) to improve FCST accuracy.
- **Limitations and necessity of correct interpretation of Radar products.**

Rainfall & Agriculture

Plant and Animal life depend on rainfall.

- Rainfall is a spatio-temporal variable parameter.
- In about 40 km radius circle, variability of rainfall from 5 to 150mm is not at all uncommon.
- Unlike SW monsoon, NE monsoon rain is pulsatory and variability is quite high.
- Dense network (2 X 2 km) may be needed for planning purposes
→ practically infeasible → an optimum network of rain gauges has been suggested (say 4km X 4km).
- But this network is also practically impossible in view of
 1. High variability of rainfall in a dimension lesser than this grid.
 2. Problem in locating sites (topographical / terrain constraints).
 3. Cost constraints.
 4. Maintenance related problems.
- Radar based rainrate estimation over a fine resolution is a probable solution to address the rainfall variability.

Radar Hydrology

- Radar's ability to see larger areas nearly simultaneously is one of the major advantages of radar technology.
- The problem of inadequate rain gauges can be addressed by Radar hydrology .
- Radar reflectivity (z) – Rain rate (R) relationship [Marshall – Palmer relationship], viz., $z = A R^b$ where 'A' and 'b' are the parameters to be estimated.
- The parameters 'A' and 'b' can vary spatially, temporally besides types of precipitation (convective / stratiform etc).
- 1000s of 'A' and 'b' are available in literature (Battan, 1973; Atlas, 1990; Rinehart, 1999; Raghavan, 2003 to name a few).

- Sample area of radar pulse (approx. $8 * 10^5 \text{ m}^2$ at 57 km) is million times larger than that of the rain gauges ($3 \text{ to } 5 * 10^{-3} \text{ m}^2$).

Radar Hydrology ... contd...

- ✓ Rain attenuation in S-band is less → useful for rain rate estimation.
- ✓ The X-band radars are unsuitable for rain rate estimation in view of very high rain attenuation.
- Desirable to have a number of low powered radars capable of measuring hydrometeors upto 100 km without much rain attenuation (especially over mountainous region).
- Such radars commensurate with the cost-effectiveness of millions of rain gauges.
- Precipitation accumulation over a period of time can be estimated using the $z - R$ relationship.

- Limitations : Issues related to calibration of Radar, DSD, rain attenuation, beam filling, Clutters and Anomalous propagation etc to be understood and addressed before using the products.

Validation of $z - R$ relationship

.... DWR, Chennai

- ❖ Developed $z - R$ relation $z=267R^{1.345}$ and used in operational set up since 2003 (Suresh et al, 2005, Mausam, p433-446).
- ❖ Time integrated (1 to 24 hours) rainrate compared with ground truth (ORG / SRRG / ARG) as a matter of routine till date.
- ❖ 80 to 95% accurate in real world scenario.

R/G location	R/G (cm)	Radar (cm)
MO, Chennai	20	18.7 – 20.0
ACWC, Chennai	16	11.5 – 14.7
Tambaram	14	9.3 – 13.3
Cholavaram	13	12.0 – 13.3
RedHills	12.0	8.0 – 9.3
Poondi	4	2.7 – 4.0
Thamaraipakkam	8	6.7 – 8.1

Radar Hydrology ..

Advantages/Limitations

Radar estimation of rainfall is useful in view of its

a) **Wide area coverage.** Supplements rain gauge measurements.

b) **High spatial and temporal resolution.**

c) **Real time measurement.**

➔ Quite useful for water resources management especially over catchments in the absence of dense R/G network.

➤ **Helps to issue Flash flood forecasting.**

➤ Helps to understand the rainfall variability in microscale.

✓ **Quite useful for physical initialization of NWP models.**

❖ **Over estimation from Bright band, Hail stones.**

62 dBZ = 639 mm/hr ; 60 dBZ = 454 mm/hr

58 dBZ = 322 mm/hr ; 56 dBZ = 229 mm/hr

INDIA METEOROLOGICAL DEPARTMENT

Physical initialization & Predictability

Tarbell (1981).

Static initialization (nondivergent initial condition) of model is inaccurate on short term precipitation forecast.

← Several hours to develop consistent vertical velocity field.

← Mesoscale moisture field cannot be resolved by U/A data.

- ✓ Divergent initialization was proposed [vertical velocity using diabatic term based on rainrate, to compute velocity potential, divergent wind components, finally geopotential (using both div /nondiv wind) to ultimately compute hydrostatic temperature].
- ✓ On meso scale, the diabatic term in the omega equation is dominant in regions of precipitation (← Radar/Satellite rainrate).
- Physical initialisation - an analysis to improve basic state variables using non-conventional data (Radar Rainrate, OLR, condensation heating rate using rain rate) - significantly improved short range FCST.
- Greater improvement possible with higher rainrate at the initial time.

Winter precipitation over Chennai

○ Radar echoes revealed that **during March, the driest month, Chennai** experienced rain in the northern and southern suburbs.

○ **Why does Chennai have water scarcity when it receives good rain even during winter ??**

suresh.imd@gmail.com

भारत मौसम विज्ञान विभाग
INDIA METEOROLOGICAL DEPARTMENT

Was it raining around Chennai during December 2002 - March 2003?

No report of rainfall from Met. office/ public / media over these areas.

suresh.imd@gmail.com

भारत मौसम विज्ञान विभाग
INDIA METEOROLOGICAL DEPARTMENT

Was it raining around Chennai during December 2002 - March 2003 ?

- Radar measurements indicate as if 20-60 cm rainfall received over an area of about 600-1600 km² around Chennai during Jan – Mar2003.
- Had there been such an accumulated rainfall, no water scarcity could have been experienced in Chennai during 2003 !!!.

suresh.imd@gmail.com

भारत मौसम विज्ञान विभाग
INDIA METEOROLOGICAL DEPARTMENT

Results of analysis on enhanced Z during Dec 2002 – March 2003

- No enhancement in reflectivity was observed over Bay of Bengal.
- The enhanced Z was observed during 0530 – 0700 and during 1700 – 1900 IST.
- The Z maximum was concentrated mostly over North and South Chennai.
- Spurious estimation from clutters is ruled out as clutter filter of 1 ms^{-1} notch-width & proper Signal quality index were activated in those scans.
- Reflectivity from pollutants (SPM) hardly worked out to -0.9 to 4dBZ only and nowhere near the 25-30dBZ observed.

suresh.imd@gmail.com

भारत मौसम विज्ञान विभाग
INDIA METEOROLOGICAL DEPARTMENT

Probable cause for enhanced Z, December – March.

The likely origin of enhanced Z was from birds (and possibly from insects).

- the time of enhanced Z coincides with the activity of birds.
- the activity of 8000 – 10000 birds over the area and period of study have been confirmed by Chennai based ornithologists and naturalists.
- Equivalent reflectivity factor (Z_e) based on volume reflectivity(η) [which depends on radar cross sections of scatterers / volume] confirms 8000-10000 migratory birds (*Jacanas, Egrets, Cormorants, Herons, black winged Stilts, Rosy Starlings*) of various cross sections ← as supported by naturalists and bird watchers.
- Computation of C_n^2 (within one hour after Sunrise and Sunset) shows that these values increase (from that computed earlier using Z as well as from RS/RW) by more than two orders of magnitude due to enhanced reflectivity caused by the migratory birds and insects.

Probable cause for enhanced Z, December – March ..contd

- In the morning (evening), the activities of birds commence during Astronomical twilight (Civil twilight), the peak activity during Civil twilight (beyond Civil twilight but well within Nautical twilight) and cease about 1 - 1½ hours after Sunrise.
- Knowledge of the source and time of clear air reflectivity may help the forecaster to improve his nowcasting capabilities.
- Mere watching radar echoes is NOT sufficient. One should understand the source of echoes.
- DWR is NOT the panacea of the meteorologist's forecasting problems.
- One should know the climatology of the place as well and continuously monitor the products (as is the case with satellite imageries as well) to interpret / understand the intricacies of data and the concept of the products (Rinehart, 1999).

[Suresh et al, 2005, Mausam, p 447-464]

suresh.imd@gmail.com

भारत मौसम विज्ञान विभाग
INDIA METEOROLOGICAL DEPARTMENT

Summary

Radar Hydrology application supplements R/G measurements. Physical initialization of high resolution rain rate improves the short range predictability.

- DWR is an efficient observation tool for nowcasting but NOT a panacea of Meteorologist's problem of weather forecasting.
- Interpretation of DWR products requires experience and vast literature survey.

Murmuration of 4000-5000 Rosy starlings at 0030Z/21.3.2019 over Pulicat lake (Chennai-SHAR) → → →

(The Hindu, Chennai 28.3.2019).
